

Title:
Visualization using RStudio and Protein dataset

Dr. Alon Friedman, Associate professor

=====

In this presentation, I will focus on *R* and visualization using Protein as my dataset.

Background:

As a platform, *R* is allocated towards statistical analysis and data visualization, but this core development consists of the extensible through packages—many of them are specialized—that are created and maintained by a developer community.

R allows us to generate visualization to extend data analysis.

I will also discuss the ***Three common strategies*** for working with Big Data in *R*:

1. Sample
2. Chunk and Pull
3. Push Compute to Data

Python vs. R

The basis of much of data science is based on statistics, data mining, and visualization. Many of the standard statistical techniques are adequately covered by Python but if you try unconventional techniques and methodologies, you will get lost. *R* is designated as a “language and environment for statistical computing and graphics” (What is R?, n.d.). There are now more than 35,000 R packages on the official repository CRAN alone! I will demonstrate how you can use GitHub to pull R packages and code to help us analyze JSONL files using the knowledge already created in *R*.

Why visualization and Big Data/Data science?

- We as humans react to visual data faster than text. (Mani, M., & Fei, S. 2017).
- The first benefit of visualization with Big Data/Data science is easier to understand the data.
- Visualization lets us distinguish the data spread over time.
- Visualization helps us recognize similarities and random connections.
- Playfair (1821) is widely considered the father of statistical graphics including the most popular graphs we use today (line, bar, circle, and pie charts).

The Bottom line is divided into Years, the Right hand line into £10,000 each.
Published as the Act directs, 1st May 1786, by W^m Playfair. Made useful 352, Strand, London.

Basic Visualization in R

R provides us basic visualization functions without any additional packages:
Those functions includes: plot: generic x-y plotting * barplot: bar plots. * hist: histograms.

* Pie charts and R code

=====

```
t=0:10  
z= exp(-t/2)  
plot(t,z)
```

R code for Histogram

```
values <- c(0.4, 0.75, 0.2, 0.6, 0.5)  
hist(values)
```

R code for pie

=====

```
values <- c(0.4, 0.75, 0.2, 0.6, 0.5)
pie(values)
```

ggplot2 breaks away from traditional data visualization techniques.

ggplot2 ggplot2 is an R package for creating graphics, based on The Grammar of Graphics. One of the things it allows us to have a Canvas background.

```
# Init Ggplot  
ggplot(midwest, aes(x=area, y=poptotal)) # area and poptotal are columns in  
'midwest'
```

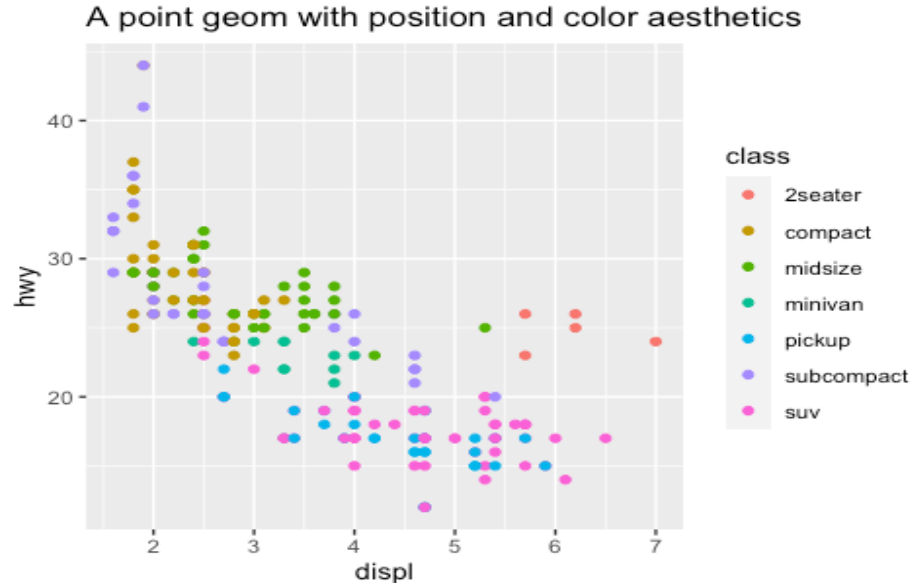

ggplot2 and Visual Grammar

Core components of the layered grammar of graphics using ggplot2.

- Data.
- Mapping.
- Statistical transformation (stat).
- Geometric object (geom).
- Position adjustment (position).

```
ggplot(data = mpg, mapping = aes(x = displ, y = hwy, color = class)) +  
  geom_point() +  
  ggtitle("A point geom with position and color aesthetics")
```

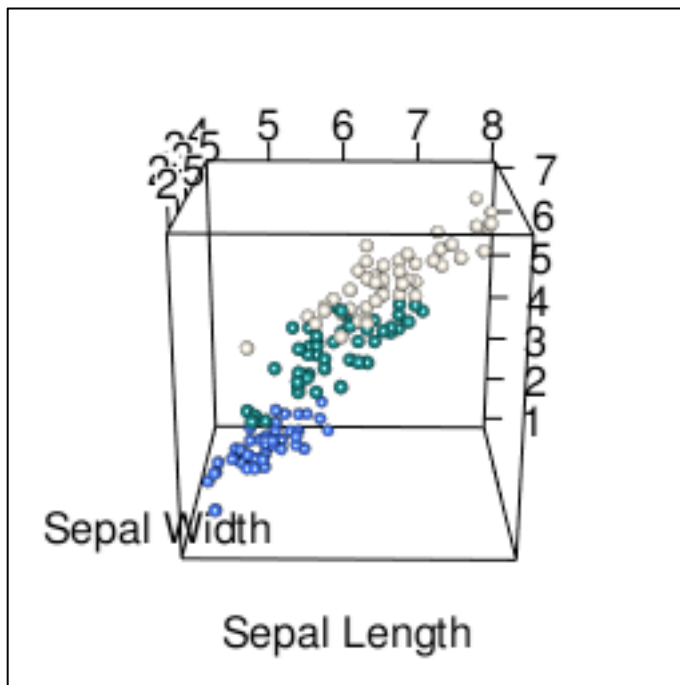

3D scatter plot

In order to build 3D plot, you need to have **3 numeric variables**, each being used on an axis. In this an example, i employed *iris* dataset. Plus I used *rgl* packages that comes with the function called *plot3d()*

```
library(rgl)
data <- iris

# Add a new column with color
mycolors <- c('royalblue1', 'darkcyan', 'oldlace')
data$color <- mycolors[ as.numeric(data$Species) ]

# Plot
par(mar=c(0,0,0,0))
plot3d(
  x=data$`Sepal.Length`, y=data$`Sepal.Width`, z=data$`Petal.Length`,
  col = data$color,
  type = 's',
  radius = .1,
  xlab="Sepal Length", ylab="Sepal Width", zlab="Petal Length")
```

Next

- Using R packages
- Importing data
- Extracting data
- Working with GitHub
- Large data files in R
- Using Visualization in this work

Using R package

R is designated as a “language and environment for statistical computing and graphics” (What is R?, n.d.). This multilayered software core development consists of the extensible through packages—many of them are specialized—that are created and maintained by a developer community.

A package is a way to organize your work in R and help share it with others.

Each of the R packages contains sets of code (called *functions*) that accomplish specific tasks. In addition, every package also includes documentation, the data score and some tests to check everything works as it should, and data sets.

Here are some of the most popular R packages

-**Tidyverse**- provides a set of functions that help you get to tidy data. For more details on dplyr <https://www.tidyverse.org>

-**dplyr**- is primarily a set of functions designed to enable dataframe manipulation of the data. For more details on dplyr <https://github.com/tidyverse/dplyr>

-**ggplot2**- is a package that helps to enhance the data visualization from your work in R. For more details on ggplot2 <https://ggplot2.tidyverse.org>.

R packages repositories

-**CRAN** - The Comprehensive R Archive Network

-**BioConductor**- is a set of repositories containing R packages used in the analysis of scientific data.

-**GitHub** - is the largest code repositories that offers version control using Git. It offers the distributed version control and source code.

GitHub

GitHub is the most popular version control system for developers of R packages.

Using *devtools* package, allow us to install the package directly from GitHub.

1. `install.packages("devtools")`
2. `library("devtools")`
3. `install_github("name of the creator of the repository/name of the package")`

Importing data

The new Rstudio interface provides easy features to import data from *csv*, *xls*, *xlsx*, *sav*, *dta*, *por*, *sas* and *stata* files. For full step by step, Rstudio provides For more details on importing data see <https://support.rstudio.com/hc/en-us/articles/218611977-Importing-Data-with-RStudio>.

JSON and R.

JSON stands for JavaScript Object Notation. These files contain the data in human-readable format, i.e. as text. Like any other file format(s), one can read as well as write into the JSON files. In order to work with JSON files in R, one needs to install the “*rjson*” package.

```
install.packages("rjson") library("rjson")
```

Extracting Data

There are many techniques for extracting data in R.

Here are the most common practices:

- Data.frame** is a list of variables of the same number of rows with unique row names, given class "data.frame"

- The most general way to subset a data frame by rows and/or columns is the base R

- Extract function** `d[rows, columns]` here *d* is the data frame.

For example:

```
data <- data.frame(x1 = 1:10,  
                  x2 = letters[1:10],  
                  x3 = "x")
```

data

```
##      x1 x2 x3  
## 1     1  a  x  
## 2     2  b  x  
## 3     3  c  x  
## 4     4  d  x  
## 5     5  e  x  
## 6     6  f  x  
## 7     7  g  x  
## 8     8  h  x  
## 9     9  i  x  
## 10    10 j  x
```

head(data)

```
##      x1 x2 x3  
## 1     1  a  x  
## 2     2  b  x  
## 3     3  c  x  
## 4     4  d  x  
## 5     5  e  x  
## 6     6  f  x
```

- Extract or Replace Parts of a Data Frame. `x[i, j, drop =]` `x[i, j] <- value` `x[[..., exact = TRUE]]`
`x[[i, j]] <- value` `x$name <- value`

Cleaning Data

What exactly is clean data? Clean data is accurate, complete, and in a format that is ready to analyze.

Characteristics of clean data include data that are:

- Free of duplicate rows/values
- Error-free (e.g. free of misspellings)
- Relevant (e.g. free of special characters)
- The appropriate data type for analysis
- Free of outliers
- and using “tidy data” structure

For more information about how to clean data, I highly recommend you to visit *Brief Introduction to the 12 Steps of Data Cleaning* [Morrow, 2013]

(<https://www.slideshare.net/jamorrow/brief-introduction-to-the-12-steps-of-evaluatio>)

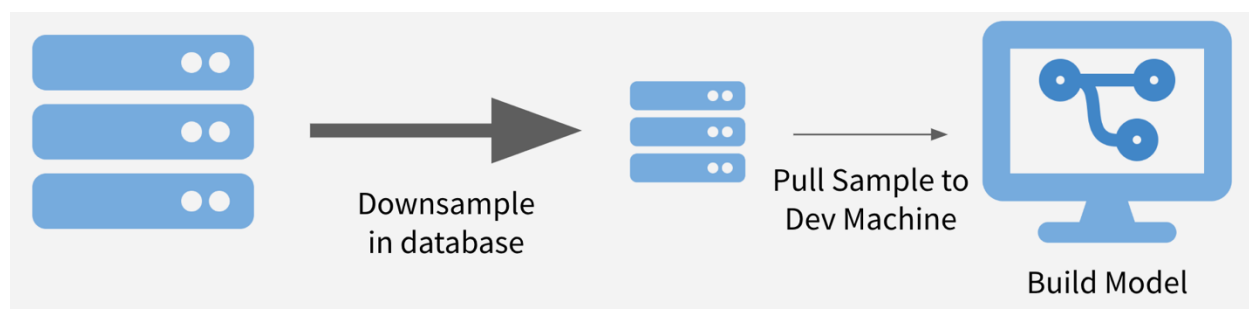

Large data files in R

R is known to have difficulties handling large data files.

The R community address this issue and here are the three strategies for working with Big Data in R. This notes are taken from Alex Gold, Rstudio bog posting. See (<https://rviews.rstudio.com/2019/07/17/3-big-data-strategies-for-r/>)

1. Sample and Model

To sample and model, you conduct a sample from your data to a size that can be easily downloaded in its entirety and create a model on the sample. Downsampling to thousands – or even hundreds of thousands – of data points can make model runtimes feasible while also maintaining statistical validity.

2. Chunk and Pull

Under this strategy, the data is divided into separable units and each unit is pulled separately and operated on serially, in parallel, or after recombining.

3. Data Compression

In this procedure, the data is compressed on the database, and only the compressed data set is moved out of the database into R. It is often possible to obtain significant speedups simply by doing summarization or filtering in the database before pulling the data into R.

-In this presentation, we will work with the entire file in the computer memory.

Additional recommendations for a faster process:

- Use *data.frame* -Use *data.table*'s package.
- Use *sqldf* function for *csv* files.
- Use a *SQLite database* and employ *dplyr*'s package.
- Convert your *csv* file to a *sqlite* database in order to query.
- Limit the number of lines you read using *fread* function under.

For example

```
size_t fread(void * buffer, size_t size, size_t count, FILE * stream)
```

In this code **buffer**: it specifies the pointer to the block of memory with a size of at least (size*count) bytes to store the objects.

size: it specifies the size of each object in bytes. size_t is an unsigned integral type.

count: it specifies the number of elements, each one with a size of size bytes.

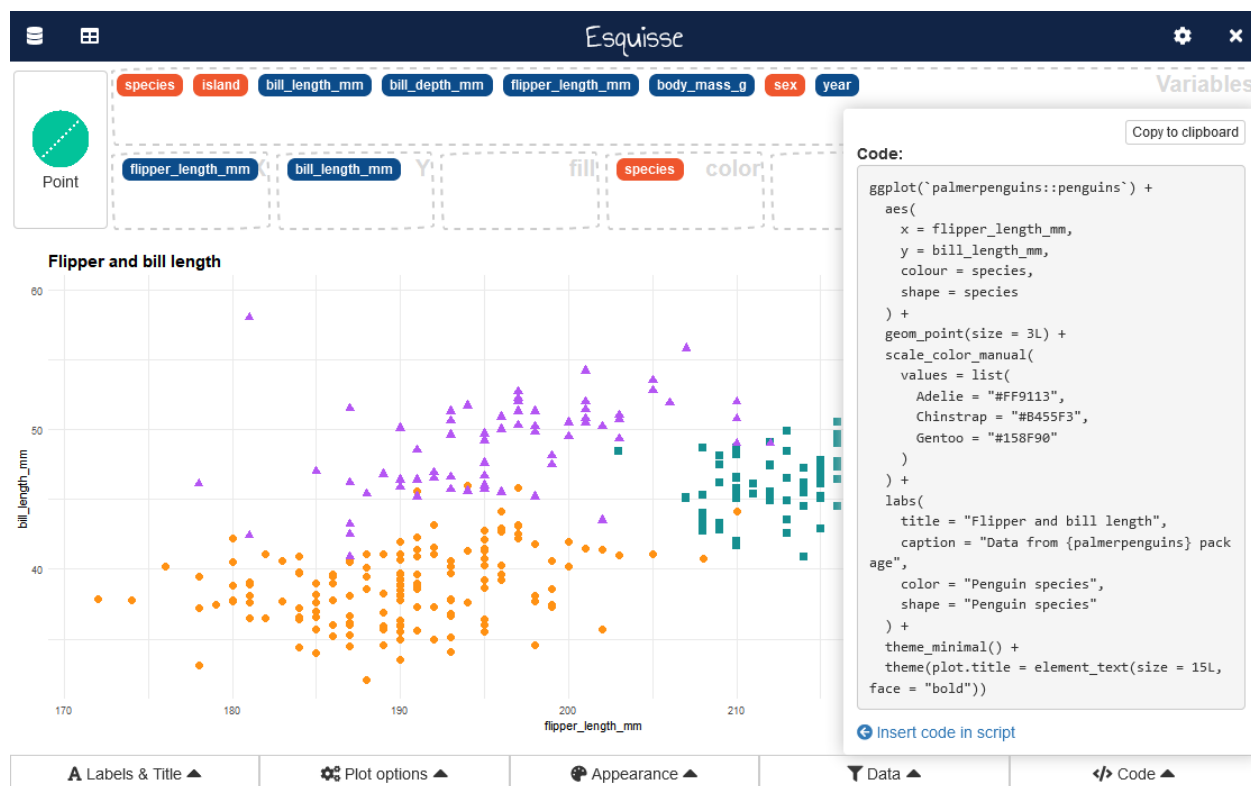

stream: it specifies the file stream to read the data from.

Using Visualization to read large data file

I will present three different files, different visualization formats and different R packages.

The list line is list of R packages we will use. The next line is calling those libraries.

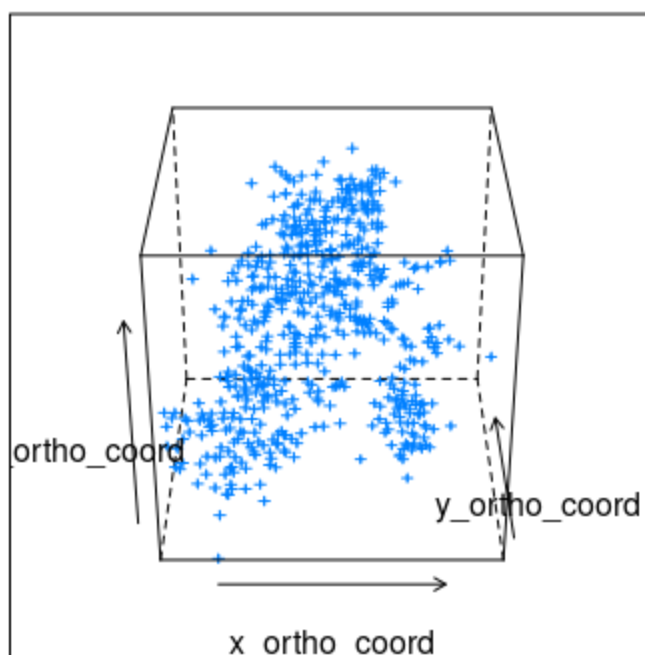

The first example is using **esquisse** package. The purpose of this add-in package is to let you explore your data quickly to extract the information they hold.

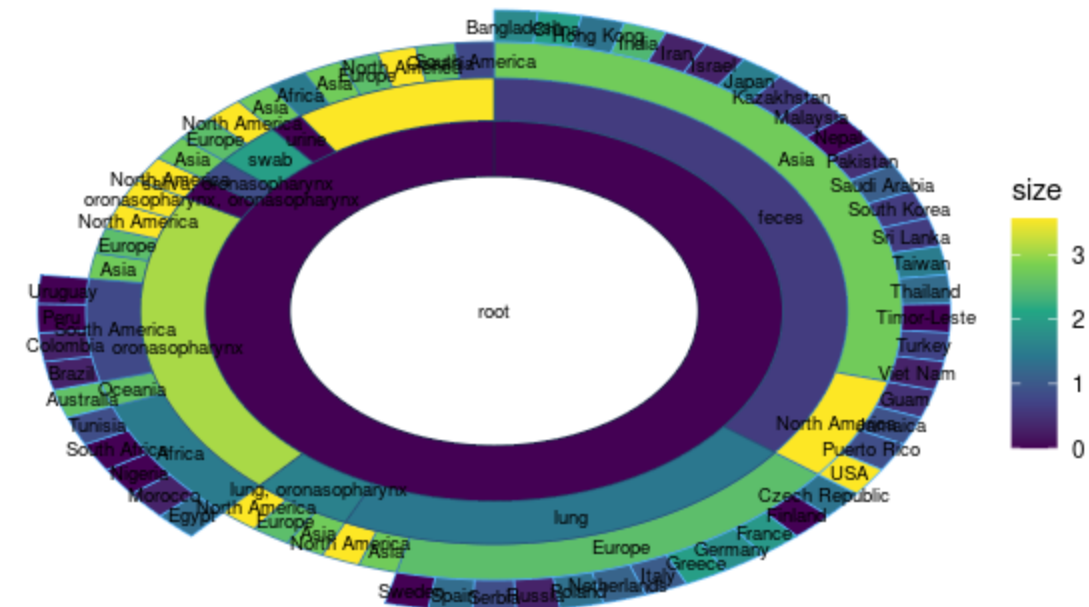

The second example is with a small dataset **without use of esquisse's package**.

PDB: 1AIE

The third and last example is with a larger data set that holds 31 megabits and 23 columns. Both data sets were taken from the *National Oceanic and Atmospheric*' database on subject of *protein*.

Your work

1. Log on to National Centers for Environmental Information
<https://www.ncdc.noaa.gov> and search your own database.
2. Convert the data you selected and insert to R.
3. Then, try to select 7 common charts including:

Scatter Plot

Histogram

Bar Chart

Box Plot

Area Chart

Heat Map

Correlogram

Scatter plot - here is example code

```
library(ggplot2)
ggplot(iris, aes(x=Sepal.Length, y=Sepal.Width)) +
  geom_point()
```

Histogram is often used for continuous variables. It captures the data into bins and frequency.

```
library(ggplot2)

# Create data
data <- data.frame(
  name=c("A", "B", "C", "D", "E") ,
  value=c(3,12,5,18,45)
)

# Barplot
ggplot(data, aes(x=name, y=value)) +
  geom_bar(stat = "identity", width=0.2)
```

Box Plot is also well recognized visual format. It allows us to combination categorical and continuous variables. R allows us to point the outliers in the data.

```
library(tidyverse)
